Open Source Voting System
Github

Written by Zach Koch

The intention is to have an all in one python script that operates on a slim Linux OS, where peoples votes are individually hashed together and encrypted into an RDF (Response Data Format)

This hash would be printed to the person with their vote information and uploaded to an online database locally, republically, and federally

In Progress:

The image loads ubuntu:20.04 right now for stability/ease.

I want to alter the current cmdline exit code(CTRL+C)

Next Steps:

Create Keys for En/Decryption and Assure the file contents are appended to a FINAL Response Data
